Ionization isomers (or coordination isomers) occur when one anionic ligand in the inner coordination sphere is replaced with the counter ion from the outer coordination sphere. A simple example of two ionization isomers are $[\text{CoCl}_6][\text{Br}]$ and $[\text{CoCl}_5\text{Br}][\text{Cl}]$.

Because transition metals are generally less electronegative than the atoms on the ligands (C, N, O, Cl, P...) that form the metal-ligand bond,

our convention is to assign both electrons in the bond to the ligand. For example, in the ferricyanide complex $[\text{Fe}(\text{CN})_6]^{3-}$, if the cyanide ligand keeps both of its electrons it is formulated as CN^- . By difference, iron must be Fe^{3+} because the charges ...
